

1. Defects of software are described and handled by using defect classification and priority.
 - a. List and describe all the classes in defect classification
 - Showstopper (X):
 - Impact of the defect is severe.
 - System cannot be tested without resolving, internal solutions may not be available.
 - Critical (C):
 - Impact of the defect is severe, BUT an internal solution is available.
 - Non-critical (N):
 - All defects not in the X and C, to be in the N category.
 - Can be solved via documentation or user training
 - b. Provide one example for each class in (a).
 - Showstopper (X)
 - Example:

The application crashes immediately upon startup, preventing all access to features and testing activities.
 -  No workaround is available; **must be fixed before proceeding.**
 - Critical (C)
 - Example:

The login page fails to redirect to the dashboard after successful authentication, but testers can still access the dashboard using a direct URL.
 -  Workaround exists, but the **defect impacts core functionality.**
 - Non-critical (N)
 - Example:

A button label is misspelled ("Submt" instead of "Submit"), but it still functions correctly.
 -  Can be **addressed** through **documentation** or **user training**.

- c. List and describe all the priority levels in defect priority.
 - High:
 - further development or testing can't occur until defect repaired
 - Medium:
 - defects need to be solved as soon as possible, it is impairing development and testing.
 - Low:
 - can be repair after more serious defect fixed
2. Define configuration management and explain why it is important.
 - A systems engineering process for **establishing and maintaining consistency** of a product's performance, functional, and physical attributes with its **requirements, design, and operational information** throughout its life.
 - or
 - A systems engineering process for keeping all software items organized and consistent during the project. It manages things like test scripts, data, software and hardware.
3. Explain the importance of configuration management.
 - Helps to **track and control changes** to files and documents
 - Make sure everyone **uses the correct and latest version**
 - **Avoid mistakes** like using old or wrong files
4. Identify configuration management activities in software testing.
 - **Identifying and defining the items** in the system,
 - **Controlling the change** of these items throughout their lifecycle
 - **Recording and reporting the status** of items and change requests
 - Verifying the **completeness and correctness** of items.
5. What is the purpose of defect reporting?
Describe the defects in software

6. If a defect cannot be solved, suggest any professional action will be taken.
 - User Training
 - Train end-users on how to manage or avoid the issue during system use.
 - Acceptance from Product Owner
 - Obtain formal sign-off from the client if the defect is to remain unresolved.

7. What is a test incident report?
 - A **written description of an incident** observed during a testing.
 - Very often an incident is referred as a defect, but incident is basically **any unexpected behavior or response** from software that requires investigation
